1.0 AN INTRODUCTION TO THE SEDD SPECIFICATION

What is the SEDD Specification?

The SEDD (Staged Electronic Data Deliverable) Specification is a specification for developing standardized electronic data deliverable formats for environmental analytical data. SEDD is designed to be Agency and Program neutral.

Each data requester develops a guide based on the SEDD specification and their technical requirements. This guide includes the Document Type Definition (DTD) or XML Schema and the complete set of instructions for developing their specific EDD format. For the most common forms of environmental analysis (e.g., GC/MS, GC), DTDs have been developed for SEDD and may be used with little or no modification.

Actual electronic data delivered as a unit is called an Electronic Data Deliverable (EDD). The analytical data delivered by laboratories to their data requesters includes sample identification, laboratory measurements, and laboratory quality control information.

What does the SEDD Specification do?

The SEDD Specification provides the framework for developing these DTDs and the resultant EDDs. Figure 1 shows a general system for the transmittal of environmental analytical data from the data generator (the analytical laboratory) to the data requester (federal or state agencies, private firms, etc.). Data are generated in the analytical laboratory and then sent to the data requester in a format required by the data requester. These data are then checked by the data requester for its format and content to ensure it meets the data requester's contractual and technical requirements.

The SEDD Specification will provide the framework for developing specific EDD formats by providing general specifications for the overall data structure of the EDD, while remaining flexible enough to be tailored for individual programmatic or agency present and future needs.

What is the purpose of this document?

This document provides guidance for data requesters developing DTDs and the resultant EDDs. This document also provides guidance to the data generators for developing EDDs.

DTD development represents a large number of choices. The SEDD Specification provides a context for making these choices and a template for the structures that comprise a well-designed DTD.

Before going any further, here are some definitions which will be used in this document.

1.1 **DEFINITIONS**

The following terms are used throughout this document:

SEDD Specification

A specification for developing standardized electronic data deliverable formats for environmental analytical data. Under this specification, a common structure and dictionary are required.

Data Requester(s)

Individual(s) or organization(s) directly responsible for requesting analytical services and data from the analytical laboratory. For purposes of this document, the data requester is assumed to be the person or organization responsible for developing the DTD. Examples of Data Requesters include Federal or State Agencies, private engineering or environmental firms, etc.

DTD (Document Type Definition)

The Document Type Definition (DTD) would give the set of rules for developing the structure and data elements for specific EDD formats. These rules are established by the data requester and the SEDD structure.

Data Generator

Individual(s) or organization(s) directly responsible for generating data. For purposes of this document, the data generator is assumed to be the person or organization responsible for producing and transmitting the EDD. Examples of Data Generators include analytical, radio analytical, or field laboratories.

EDD (Electronic Data Deliverable)

An electronic file created by a data generator (usually the analytical laboratory) for transmitting and reporting analytical data.

XML (eXtensible Mark-up Language)

This is a standard devised by the World Wide Web Consortium (W3C) and provides a common approach to representing information over the Web. It is a language for describing data. It is not owned by any one vendor and thus remains an open standard. It is text based so it can be processed by any platform. The SEDD Specification uses XML as it's transmission standard.

Elements

An element consists of a start tag, content, and an end tag. An element may contain other elements. The SEDD Data Dictionary contains the list of tags that developers may use. The SEDD Structure specifies relationships between certain elements from the Dictionary.

Data Dictionary

The data dictionary contains the definitions of the defined data elements along with where in the structure they can be used.

1.2 RELATIONSHIP OF A DTD TO THE SEDD SPECIFICATION

The SEDD Specification gives the requirements for developing DTDs and the resultant EDDs for reporting data to meet data requester's (e.g., a Federal Agency) needs.

Examples of actual DTDs and the resultant EDDs are presented in separate files in Appendix B.

The SEDD Specification is flexible in that it can satisfy diverse requirements. The SEDD Specification uses a data model based on analytical activities as a starting point for requesting data deliverables.

The SEDD Specification uses names for nodes and data elements to describe diverse types of laboratory activities. To take full advantage of the standardization available from the SEDD Specification, data requesters shall use these generalized names in their DTDs. A data dictionary listing these generalized names is presented in Appendix A. A DTD specifies which of the SEDD Specification nodes and data elements are required.

If after careful review of the SEDD structure and the Data Dictionary, a data requester is convinced that a particular requirement of their program is not addressed, implementation specific elements and nodes may be added to the data requester's DTD. The data requester needs to be aware that implementation specific elements and nodes reduce the ability of programs to share data. Data requesters should also present their specific needs to other programs using SEDD, for possible future incorporation into the SEDD Specification.

A DTD rarely requires all of the information available in the SEDD Specification. When necessary, a data requester can require additional information. However, all DTDs and the resultant EDDs created using the SEDD Specification will use the same structure and data dictionary.

This section, in conjunction with Sections 2, 3, and the SEDD Data Element Dictionary, constitutes the Staged Electronic Data Deliverable (SEDD) specification for developing the Document Type Definition (DTD) and the resultant EDD.

This SEDD Specification document is not a comprehensive specification for a specific DTD and EDD format. Specific DTDs and the resultant EDDs must still be fully developed and defined by the data requester using the SEDD specification as a reference. In order to derive the greatest benefits from the XML technology, data requesters must utilize both the SEDD Specification structure and the SEDD Specification data element dictionary.

Example DTDs are now being developed for the major environmental analytical methods. It is strongly recommended that data requesters use these generic DTDs for their programs instead of creating new ones.

1.3 OVERVIEW OF AN EDD FILE CREATED USING A DTD BASED ON THE SEDD SPECIFICATION

A SEDD Specification compatible EDD is a text file that reports data in the form of "elements." As illustrated in Figure 2, there are two kinds of elements - data elements and nodes.

Data elements contain data and have the following parts: a data element name (start tag), a data element value, and a data element name (end tag). The data element name is a descriptive label. The data element value is the associated value.

Nodes contain data elements. Nodes also have a start tag and an end tag. Data elements are contained between these tags. Figure 2 also shows an example of data elements within a node.

The nodes are arranged in a hierarchy. The level of a node in the hierarchy partially determines its meaning.

1.4 THE SEDD SPECIFICATION HIERARCHY

The SEDD Specification hierarchy is based on a model of laboratory activities, the linkages between them, and the data these activities produce. For example, as shown in Figure 3, each sample analyzed by one method typically has several results (several ReportedResult nodes under one SamplePlusMethod node), one for each analyte determined by the method (e.g., a suite of volatile organic compounds). A result is the "answer" provided by the laboratory (e.g., the concentration of dichloromethane is 50 ug/L). These results depend on measurements made during one or more analyses (e.g., dual column GC). As needed, details about each analyte in each analysis are reported at another level in the hierarchy.

Another important part of the model distinguishes between samples and instrument quality control (QC). Samples have results in units associated with a real matrix. InstrumentQC does not (e.g., calibrations). As Figure 3 shows, the InstrumentQC node has the same analysis-analyte structure as the SamplePlusMethod node, but there is no separate ReportedResult node.

To take full advantage of the standardization available from the SEDD Specification, data requesters shall use these structures in their DTDs. To assist data requesters, the SEDD Specification structure can be implemented in three primary stages depending upon the level of detail the data requester needs in the EDD.

Stage 1 contains the minimum number of nodes and data elements to transmit "results-only" data. Only limited method QC data (or no QC data) would be reported in Stage 1. The Stage 1 structure is presented in Figure 4.

Stage 2 builds on Stage 1 by adding method (Stage 2a) and instrument (Stage 2b) quality control data. The Stage 2a structure is presented in Figure 5 and the Stage 2b structure is presented in Figure 6.

Stage 3 builds on Stage 2 by adding additional measurement data to allow for the independent recalculation of the reported results. The Stage 3 structure is presented in Figure 7.

1.5 USE OF THE SEDD SPECIFICATION BY THE DATA REQUESTER

For the most common forms of environmental analysis, program-neutral DTDs already exist and may be used. Program-specific requirements would be addressed in the instructions to the data providers.

To create the DTD, the data requester will need to assess the current and future data needs of their program. Data requesters should evaluate which data elements (fields) they currently receive from their laboratories, either in an electronic deliverable or on a hardcopy form. Data requesters should also evaluate the level of assessment they need to apply to the data (e.g., check completeness only, or confirm calculated values). Based on this evaluation, data requesters then select the appropriate stage from the SEDD structure. This forms the basis for creating the node elements in the DTD using the required linkages.

Based on the specific data items required by the program, the data requester then adds the corresponding data elements from the Data Dictionary to the appropriate node(s).

The DTD may also be used to define acceptable values for some of the elements. Data requesters may wish a certain value to be constant (fixed), or to come from a limited set of possible values. Developers should look under "Attributes" in an XML reference source for further details.

In addition to the DTD, the data requester must also specify the appropriate formats for each element. This would include details on identifying samples, methods, and projects. This would also include specifying the minimum precision for measurements and results and the maximum

length of any reported value.

- Define the level of detail required (e.g., Stage 1, Stage 2a, Stage 2b, Stage 3) given in Section 1.
- Use the SEDD specification (i.e., use the selected stage which must include the required data elements, the linkages between them, and the data dictionary for defining all data elements).
- Define all valid values associated with appropriate data elements. Some elements may be
 restricted to a single valid value while others could have many valid values. For example the
 data element ResultUnits could have the following valid values associated with it: ug/L,
 ug/Kg, mg/L, mg/Kg, etc. A data requester may decide to only allow ug/L for Volatile
 Organics in a water matrix.

To assist the data generator in creating the resultant EDD, the data requester will also need to:

- Make the DTD and program specifications available to the data generator.
- Work with the data generator to clarify which specific data items already being supplied in a deliverable correspond to which specific SEDD data elements.

Sections 2 and 3 present the basic information to create an EDD based on the SEDD specification. Each data requester and data generator must become familiar with the guidelines and requirements given in these two sections. Once they become familiar with the guidelines, specific DTDs and special instructions can be created by the data requester. The data generator would use this information to create the EDD.

Section 2 gives the basic rules for presentation of data in each data element, the hierarchy of the elements within the DTD and the resultant EDD, and the overall EDD file which must meet XML requirements.

Section 3 describes some of the key concepts underlying the SEDD Specification analytical model.

NOTE: Sections 2 and 3 are not meant to be tutorials in XML technology. Only basic XML rules as applicable to the SEDD Specification are summarized. Both the data requester and data generator must be familiar with XML in order to correctly apply the SEDD Specification.

SEDD Draft - VERSION 5.0 August, 2003

2.0 SEDD SPECIFICATION SYNTAX, REQUIRED DATA ELEMENTS, AND DATA ELEMENT VALUE FORMATS

This section gives the structural and data representation rules for the SEDD Specification, along with the Required Data Elements, and the formats for data element values. This section is divided into three subsections:

Section 2.1 Syntax

Section 2.2 Required Data Elements

Section 2.3 Data Element Value Formats

Data can be transferred between a data generator and a data requester using XML technology only if the specifications regarding the data format have been worked out between the two parties, prior to transmission of data (in the form of an XML file). The SEDD Specification gives the basis of the format for transmission of analytical data by clearly defining: the overall data structure, data elements, and relationships between the data elements.

NOTE: Most of the examples given in Sections 2 and 3 pertain to Stages 2b and 3 of the SEDD Specification. At present, most laboratories deliver Electronic Data Deliverables (EDDs) equivalent to Stage 2a of the SEDD Specification (sample results plus method quality control data - Figure 5). Pilot studies have demonstrated that most laboratories can implement EDD's based on a Stage 2a SEDD Specification format within a few months. Laboratories can then build on the Stage 2a EDDs to create and deliver Stage 2b (Figure 6) or Stage 3 (Figure 7) EDDs by simply adding additional nodes and data elements to the Stage 2a EDD (as data requestor needs change).

2.1 SYNTAX

Syntax is defined as the rules for representation of data and structure. This section describes the syntax for the following components of SEDD Specification-compatible EDD as well as the overall file syntax:

- Characters and Lines (Section 2.1.1)
- Elements, Names, and Values (Section 2.1.2)
- SEDD Specification Hierarchy (Section 2.1.3)
- XML File Syntax (Section 2.1.4)

Figure 8 is a graphical representation of a SEDD Specification-compatible EDD for a common organics method. This figure illustrates the major components discussed in the syntax section and provides a useful frame of reference for visualizing the relationship(s) between components. Figure 8 is not a complete example of the SEDD Specification syntax or data element list.

2.1.1 Character and Line Syntax

Characters and Lines

- An EDD is a string of characters in a series of lines.
- The specific character set used would be specified in the opening XML declaration statement to call specific data linkage library modules/parsers within the operating system program of the computer. The encoding called UTF-8 (Unicode Transformation Format 8-bit form) will be the default used for SEDD. The use of other character codes is possible. The UTF-8 character set uses all 7-bit ASCII codes for values 0 through 127 and uses the ISO-8859-1 (Latin-1) codes for values 128 through 255.
- There are six basic types of lines:
 - 1. **XML declaration line**: This is the first line in an XML document. Consists of optional leading spaces; a less than sign followed by a question mark followed by the letters xml; the xml declaration statements; a question mark followed by the greater than sign (e.g., <?xml version="1.0" ?>).
 - 2. **Document type declaration lines**: This is generally the second line in an XML document. Consists of optional leading spaces; a less than sign followed by an exclamation mark followed by the letters DOCTYPE; the DOCTYPE declaration statement; the greater than sign (e.g., <!DOCTYPE Header SYSTEM "OrganicGeneral_3_1.dtd">).
 - 3. **Blank lines**: Contain no characters. Blank lines can occur anywhere in an EDD. They can be used for visual formatting to aid browsers.
 - 4. **Comment lines**: Consist of optional leading spaces; a less than sign, the exclamation mark, two dashes; followed by the comment; followed by two dashes and greater than sign (e.g., <!-- This is a comment line. -->). A comment line does not need to include the word "comment".

Comment lines can occur anywhere in an EDD. Their content is not part of the information to be delivered by the EDD. They can be used to annotate an EDD for a browser and might be printed as part of a status report by a program that reads the EDD.

NOTE: It is important to distinguish a <!-- comment line --> from actual comments made as part of the official EDD itself. Within an EDD, the Comment data element is

used to convey information that may be important for the proper interpretation of the data presented (example: <Comment>This is a comment.</Comment).)

- 5. **Data element lines**: Consist of optional leading spaces; a less than sign followed by a data element tag name followed by a greater than sign; the data element value; a less than sign followed by the forward slash sign followed by a data element tag name followed by the greater than sign (e.g., <DataElementTag>value</DataElementTag>). A data element usually delivers a
 - <DataElementTag>value
 /DataElementTag>). A data element usually delivers a single piece of information.
- 6. **Nodes**: Consist of optional leading spaces; a less than sign followed by a node tag name followed by a greater than sign (e.g., <NodeTag>). A closing node tag name must also be used later in the EDD and consists of optional leading spaces; a less than sign, followed by a forward slash, followed by the same node tag name, followed by the greater than sign (e.g., </NodeTag>). A node contains other data elements.
- Optional leading spaces in lines are allowed so EDD data can be indented to improve browseability.

2.1.2 Element Syntax: Data Elements, Names, and Values

Data Elements

- Definitions for the SEDD specification data elements are provided in Appendix A.
- A data element tag consists of a start data element tag name followed by the data element value content followed by an end data element tag name (e.g., <Result>24.2</Result>). A data element usually delivers a single piece of information. Data elements are sometimes called fields.
- Spaces are not allowed unless they are an integral part of the data element value.
- The SEDD Specification has no rules forbidding the use of any data elements and data requesters cannot add any such rules. If data requesters receive more data elements than originally requested, the data requester should ignore these additional data elements.

Data Element Names

• A data element name is a string of alphanumeric (A-Z, a-z, 0-9) characters. A name identifies the data delivered by a data element.

- A name should be limited to a maximum of 30 characters.
- Character case is significant in names. The first letter of all words used in data element names must be capitalized. Example: AnalyzedDate would be acceptable while Analyzeddate would not.
- Data element names defined in SEDD are listed in Appendix A with a description of their usage.
- Implementation-defined names are allowed. They must begin with the word "New". It is recommended that an identifier for the implementation (i.e., the agency responsible for the data) follow the word "New" (e.g., 'NewEPANewElement'). This will prevent conflicts across formats when implementation-specific names have been added. Useful implementation-defined names will be incorporated in later versions of SEDD under SEDD assigned names in the Data Dictionary. Data requesters are urged to carefully check the Data Dictionary to ensure that the needed data element is not already present in the dictionary under another name.
- Names should be spelled-out and each word should have its first letter capitalized (e.g., 'ResultUnits') using the Upper Camel Case (UCC) convention. Excessive abbreviation should be avoided.

Data Element Values

• A data element value can contain any string of characters allowed in a line, as restricted by rules defined by the data requester. A value is the data delivered by a data element.

NOTE: Part of the definition of a name is a possible restriction on the format of values associated with it, such as numeric or date formats. Section 2.3 defines these formats.

- By SEDD rules, the length of the value is specified by the data requester.
- The value begins immediately after the starting data element tag name. In particular, any spaces after this starting tag and before the ending tag are part of the value.
- A value can be null (contain no characters). Null values would be reported on a single line using the following format: optional leading spaces; a less than sign, followed by the data element tag name, followed by a forward slash, followed by the greater than sign (e.g., <DataElementTag/>).

Nodes

- A node element consists of an opening node tag and a closing node tag which are located on separate lines within the EDD. The opening node tag is a less than sign followed by a node tag name followed by a greater than sign (e.g., <NodeTag>). A closing node tag name must also be used later in the EDD and consists of a less than sign, followed by a forward slash, followed by the same node tag name, followed by the greater than sign (e.g., </NodeTag>).
- The first node encountered in the EDD is referred to as the root node. This node can only be used once. All data delivered in the EDD must fall within the opening root node (e.g., </Header>) and the closing root node (e.g., </Header>).

Node Element Names

- A node element name is a string of alphanumeric (A-Z, a-z, 0-9) characters.
- A name should be limited to a maximum of 30 characters.
- Character case is significant in names. The first letter of all words used in node element names must be capitalized. Example: SamplePlusMethod would be acceptable while SampleplusMethod would not.
- The following are SEDD Specification defined node element names and a description of the intended use of the associated elements.

Analysis Describes one complete sequence of events, from taking a

sample aliquot and preparation through measurement, defined

as part of one method.

Analysis Group Links several analyses used to compute results for one method.

Analyte Per-analyte data from one analysis.

AnalyteComparison Describes the effects of potentially interfering analytes on a peak

(e.g., ICP Interelement Correction factors).

Handling Describes any manipulation of the sample prior to taking an

aliquot (e.g., filtering, ashing, leaching).

Header Carries information for the reader/parser of an EDD data

stream.

InstrumentQC Describes QC analyses that do not yield results

(concentrations). These data are usually about instrument or process QC (e.g., initial and continuing calibration data).

Peak Reports an actual measurement made during one analysis of

one analyte.

PeakComparison Describes cross-peak comparisons [e.g., abundance ratios and

inter-peak resolutions].

PreparationPlusCleanup Describes a preparation or cleanup as part of an

analysis or an independent method.

ReportedResult Contains the actual results of a method (analyte

identification and computed final results).

SamplePlusMethod Contains data about the characteristics of one sample analyzed

under the criteria of one method.

• For the purposes of this SEDD specification, implementation-defined nodes are not allowed.

• Node elements should be spelled-out and each word should have its first letter capitalized (e.g., 'ResultUnits') using the Upper Camel Case (UCC) convention. Excessive abbreviation should be avoided.

Nodes Elements

- A node definition begins at a node definition line and continues until the closing node definition line is encountered.
- The contents of a node are the node definition line that starts it, all data elements and other nodes within it, and the node definition line that ends it. In particular, blank and comment lines (<!-- Comments -->, as opposed to Comment data elements) are not part of any node.
- Most data element names can only be used in specific nodes (See Appendix A). However, some data element names may appear in more than one node, possibly with slightly different definitions.

- A data element name may not appear more than once in any instance of a node.
- With the exception of data elements denoted as required by the SEDD specification (see Section 2.2) and those specified as required by a SEDD-compatible EDD implementation, no data element is required to appear in an EDD.
- SEDD specification has no rules restricting the order of data elements in nodes and data requesters cannot add any such rules.

2.1.3 SEDD Hierarchy, Header and Dependent Data Element Syntax

- SEDD specification elements are arranged in a hierarchy. Figure 7 defines this hierarchy. As implied by the term hierarchy, nodes at any level can repeat as many times as needed.
- Subject to the rules associated with the hierarchy, there are no restrictions on the number, type, and order of nodes in an EDD and a data requester cannot add any. For example, an empty EDD is valid, if not useful. Data requesters may choose to ignore nodes they do not recognize or are not interested in.
- Nodes with identical content cannot be repeated. For example, a SamplePlusMethod
 node could not be repeated before each ReportedResult node associated with it. It is
 more efficient to only have one SamplePlusMethod node for all associated Results'
 nodes.

NOTE: Data requesters need to check an EDD for global consistency of all potentially redundant data

Header Nodes

- A Header node is always the first node in an EDD. It provides the information (e.g., EDD version and implementation identification) needed to process the EDD reliably.
- An EDD (e.g., a disk file), may have multiple Header nodes as long as each header is unique. Data processing must start fresh at each new Header node.
- If two valid EDDs are concatenated (i.e., two data files with different Header nodes are appended in one file), the result is one valid EDD.

Other Nodes

- In an EDD, all other nodes must be preceded by at least one node at each higher level. Figure 7 defines the dependencies between these nodes. For example, the SamplePlusMethod node is dependent on a Header node.
- Any given node is said to be associated with the closest preceding node at each higher level in an EDD.
- The pattern of associated higher-level nodes must match the same pattern as in Figure 7. For example, in order to have a valid ReportedResult node in an EDD, it must be preceded by a Header node and a SamplePlusMethod node, as shown in Figure 7. There cannot be an InstrumentQC node between the ReportedResult and SamplePlusMethod nodes. Otherwise, the ReportedResult node would not relate to a sample. This concept is called nesting. All nodes must be properly nested.
- When more than one node of a higher level and identical type precedes another node, the dependent node is related to the nearest higher order node as shown in the following example.

EXAMPLE:

```
<Header>
<!-- Header Node - Beginning Tag -->
<SamplePlusMethod>
   <!-- First SamplePlusMethod node - Beginning Tag -->
      <ReportedResult>
      </ReportedResult>
      <!-- Associated with the first SamplePlusMethod node -->
      <ReportedResult>
      </ReportedResult>
      <!-- Associated with the first SamplePlusMethod node-->
   </SamplePlusMethod>
   <!-- First SamplePlusMethod node - Ending Tag -->
   <SamplePlusMethod>
   <!-- Second SamplePlusMethod node - Beginning Tag -->
      <ReportedResult>
      </ReportedResult>
      <!-- associated with the second SamplePlusMethod node -->
   </SamplePlusMethod>
   <!-- Second SamplePlusMethod node - Ending Tag -->
</Header>
<!-- Header node - Ending Tag -->
```

• While the order of nodes at different levels is important in the EDD, the order of nodes at the same level is not. This is shown in the following examples, where the ReportedResult and Analysis Nodes are at the same level.

EXAMPLE 1:

```
<Header>
   <SamplePlusMethod>
      <ReportedResult>
      </ReportedResult>
      <ReportedResult>
      </ReportedResult>
      <ReportedResult>
      </ReportedResult>
      <Analysis>
      </Analysis>
   </SamplePlusMethod>
</Header>
EXAMPLE 2:
<Header>
   <SamplePlusMethod>
      <ReportedResult>
      </ReportedResult>
      <Analysis>
      </Analysis>
      <ReportedResult>
      </ReportedResult>
      <ReportedResult>
      </ReportedResult>
   </SamplePlusMethod>
</Header>
```

These two examples are identical in meaning, but differ in order. All of the ReportedResult nodes in both examples associate, hierarchically, to the preceding SamplePlusMethod node. The Analysis node in each example also belongs, hierarchically, to the same SamplePlusMethod node. The Analysis node does not modify any of the ReportedResult nodes in the second example, even though it precedes it. This is because the Analysis node is not of a higher level than the ReportedResult node.

2.1.4 XML File Syntax

- Data will be delivered from data generators to their data requesters as XML documents. These XML documents will be both well-formed and valid data files.
- A well-formed XML document follows all of the official XML rules as defined by the World Wide Web Consortium (W3C). Many of these rules have already been discussed in previous sections. Data requesters are encouraged to acquaint themselves further with XML using some of the many resources available at this time.
- A valid XML document is a document that follows the Document Type Definition (DTD) file or XML Schema as established by the data requester. The DTD gives the hierarchical structure and states what data elements will be required for a given application.

2.2 REQUIRED DATA ELEMENTS

A few data elements are required to have non-null values to properly and uniquely identify the reported data. If a node is not required, any data element it may contain is not required. The SEDD Specification has four types of required data elements: required, conditionally required, required for traceability, and required for portability.

Figure 9 identifies the data elements required in a Header node. Figures 10 and 11 identify the data elements required for SamplePlusMethod and InstrumentQC nodes, respectively. Footnotes in these figures classify each data element using the above types. These figures are presented as a useful summary of the SEDD Specification hierarchy and key data elements. Appendix A contains the current SEDD specifications of required data elements.

2.2.1 Required Data Elements

Required data elements are the basis for reliable identification of EDD data by the data requestor. Examples include ClientMethodID, ClientSampleID, and ClientAnalyteID. These data elements MUST be present in a valid EDD.

Conditionally Required Data Elements

Conditionally required data elements also are the basis for identification and linkage of data, but are not required in all cases. Examples include QCType, required for QC samples; AnalysisType, required when one method involves multiple types of analyses; and AnalyteType, required for non-standard analytes such as surrogates and spikes. Based on rules specified for each data element in Appendix A, these data elements must be present in a

valid EDD.

Data Elements Required for Traceability (including QC)

The SEDD Specification has standard data elements to use when traceability back into the laboratory's process is desired. Examples include LabSampleID and LabAnalyteID. These data elements are not formally required by the SEDD Specification, but are suggested as likely to be required in the instructions from the data requester to the data generator.

Data Elements Required for Portability (including QC)

The SEDD Specification has standard data elements to use when portability of data across sites and/or data requesters is desired. Examples include ClientID, QCCategory, and QCLinkage. These data elements are not required by the SEDD Specification, but are suggested as likely to be required in the instructions from the data requester to the data generator.

NOTE 1: The SEDD specification requires the use of all required and conditionally required data elements. Data requesters may require additional data elements based on program needs.

NOTE 2: For consistency, the SEDD Specification has required fields in many nodes that serve to uniquely identify the data. For example, the PeakID data element in a Peak node is a required data element. It is needed to uniquely identify the peak in a GC/MS analysis. A reasonable value for the PeakID data element is the mass of the peak quantitated.

NOTE 3: There are some situations where no unique values exist for the required data element. For example, the ClientAnalyteID data element in a ReportedResult node is a required data element. However, there would be no real ClientAnalyteID for a Tentatively Identified Compound (TIC) as might be reported during a GC/MS analysis. In this situation the data requester must define how this data element will be used for TICs (i.e., ClientAnalyteID = Unknown Hydrocarbon01).

As noted in the beginning of this section, the data requester must specify the values for these required data elements.

2.3 DATA ELEMENT VALUE FORMATS

There are five different types of data that can be entered into a given data element. These five types are the data element value formats. These formats are Text, Identifier, Limited List, Numeric, and Date. The Data Dictionary (Appendix A) gives the format for each data element.

The examples given below are a partial list of the most commonly used formats. The data requester must specify the exact format of each data element depending on program needs.

2.3.1 Text

- Text format allows any value consistent with the syntax of a line. Case is significant in Text format so that "Test", "TEST", and "tEst" are all different values for a Text data element. If data is to be parsed to a database, this may be less of an issue.
- Leading and trailing spaces are significant in Text data element values.

2.3.2 Identifier

- Identifier format is a restricted version of Text format. Typically, these values use a restricted character set. The data requester should provide instructions for each data element with this format.
- A suggestion is that characters be restricted to alphabetic characters, digits, the underscore character, and the dash character and that case not be treated as significant. Identifiers can have further restrictions, such as check digits in CAS numbers or certain required patterns of alphabetic and numeric characters.

2.3.3 Limited List

• Limited list format is another restricted version of Text format. Typically, these values are limited to a short list of valid values. The DTD should specify valid values for each data element with this format. Valid values may depend on the value of other data elements. For example, allowed values for ResultUnits data element would typically depend on the MatrixID data element.

2.3.4 Numeric

- Numeric format includes any of the following formats:
 - ► **Integer**: leading spaces, a minus sign, a string of digits and trailing spaces, with all subparts optional. The value is interpreted as a whole number.
 - ▶ **Decimal**: leading spaces, a minus sign, a string of digits, a decimal point, another string of digits and trailing spaces, with all parts but the decimal point optional. The value is interpreted as a real number.

- **Exponential**: leading spaces, a minus sign, a string of digits, a decimal point, another string of digits, a string of spaces, the letter "E" or "e", a string of spaces, a plus or minus sign, a string of digits and trailing spaces.
- A data requester should be prepared to accept any of the possible numeric formats. A data requester must be prepared to read all three formats within the same data stream. However the data requester can specify rules for this format.

NOTE 1: The same number can be expressed in an EDD in the following ways and all are allowable:

12345 Integer format12345.000 Decimal format12345E 0 Exponential format with a zero exponent

Any of these values preceded by a minus sign are valid numbers.

NOTE 2: Legal values for zero include, but are not limited to:

0 0.0 0.0e0

- The SEDD Specification by itself does not limit the precision of numbers. Data requesters should specify minimum acceptable significant digits and/or precision for every numeric data element used. It is permissible for data generators to report greater precision than specified in a DTD.
- The SEDD Specification does not specify rounding rules. This has to be specified by the data requester.
- A null value for a numeric data element represents a totally blank value, which is not considered equivalent to the number zero.

2.3.5 Date

• The date format includes, but is not limited to, the following:

MM/DD/YY HH:mm:SS MM/DD/YY HHmmSS MM/DD/YYYY HH:mm:SS MM/DD/YYYY HHmmSS YYMMDD HH:mm:SS YYMMDD HHmmSS YYYYMMDD HH:mm:SS YYYYMMDD HHmmSS

where:

MM = month DD = day YY = last two digits of the year YYYY = four digits of the year HH = hour in 24 hour format mm = minutes SS = seconds

- The time portion of a date, with any preceding space, is optional unless required by a data requester for specific data elements. The seconds portion of the time, with any colon, is similarly optional.
- All date format values in the data stream following a Header parent data element must be
 in the same date format. This format is specified by the DateFormat data element in the
 Header node. (See Appendix A). If no date format is specified, the default format
 YYYYMMDD HHmmSS is used.

3.0 CONCEPTS AND RELATIONSHIPS

Methods used for the analysis of environmental samples are complicated procedures. They include sample preparation (digestion or extraction), cleanup of sample extracts prior to analysis, and the actual instrumental analysis. There are many associations for a single sample analysis that have to be captured in a unique way if the whole process has to be reconstructed. This is especially important if the data requester wants to clearly link all Quality Control (QC) data with the sample result.

Describing associations among data elements is essential for an EDD to be useful. Because of the variety of batches, groupings, linkages, and comparisons needed for each data requester, specifying a DTD and the resultant EDD that correctly describes a method can be difficult. Section 3.1 describes some of the concepts underlying the SEDD Specification, namely:

• Samples (Section 3.1.1)

- Method QC Sample (Section 3.1.4)
- Instrument QC (Section 3.1.2)
- Analysis (Section 3.1.5)

Method (Section 3.1.3)

• Results (Section 3.1.6)

Section 3.2 provides a discussion of the more complicated analytical relationships within the SEDD Specification. Batches typically involve linking the Method Quality Control samples (e.g., Laboratory Control Samples, Method Blanks, Matrix Spikes) analyzed to the regular field samples. Analysis Groups (under the SamplePlusMethod node) are used whenever the final reported result for a field sample is computed from more than one separate analysis result (reported as intermediate results of the sample aliquot) as in the case of Method of Standard Additions for Inorganic Analysis. Analysis Groups (under the InstrumentQC node) are used whenever multi-point initial calibration curves are determined. QC Linkages specify which batch types are used to link QC samples to regular field samples. Comparisons are used to relate individual measurements to other reference measurements for Quality Control purposes. The remainder of Section 3 is divided into the following sections:

- Batches (Section 3.2.1)
- Analysis Groups (Section 3.2.2)
- QC Categories and QC Linkages (Section 3.2.3)
- Comparisons Peak and Analyte (Section 3.2.4)

This section makes liberal use of examples drawn from actual EDDs developed under this specification. Examples in this section have been formatted to aid readability. Formatting conventions need not be adopted when preparing an EDD. While reviewing the following concepts and analytical relationships, keep Figure 7 handy as a reference for the hierarchy of the

nodes in the SEDD Specification.

3.1 CONCEPTS

3.1.1 Samples

• A sample is defined in the SEDD Specification as any substance given a sample number or identifier. This includes ones sent by a data requester to the data generator (e.g., an analytical laboratory) for analysis and certain Method QC samples (e.g., Laboratory Control Samples, Method Blanks) generated by the data generator (See Section 3.1.4, below). In a SEDD Specification-compatible EDD, a sample is reported in SamplePlusMethod and related nodes (all nodes located below the SamplePlusMethod node in the hierarchy - see Figure 7) based on the application of one or more methods.

NOTE: The SEDD Specification does not have a per-sample node. This is because the notion of what a "sample" is as reported in an EDD is ambiguous. For example, the sample might be what is identified by the following data elements within the SamplePlusMethod node: ClientSampleID, FieldSampleID, or LabSampleID. In real cases involving multiple methods, handlings, and reanalyses, these data elements may have different values.

The SEDD Specification uses the SamplePlusMethod node as its highest-level of reporting for samples. The association between the method and a sample must be clear to both the data requester and the data generator. This association is NOT necessarily provided as part of the DTD and must be provided by the data requester in their instructions to the data generator.

• Here is an example of a sample definition.

Some programs may report a dilution of a sample separately from its original (i.e., in two separate SamplePlusMethod nodes) with a distinct ClientSampleID data element and a separate set of results in each node. When a program reports a dilution of a sample separately from its original in a SEDD Specification-compatible implementation, then two separate SamplePlusMethod nodes will be used, one node to report the results of the original sample and the second node to report the results of the diluted sample. There will be only one Analysis node under each SamplePlusMethod node. In contrast, other programs may consider dilutions to be internal to the methods and only one set of selected results per original sample be reported from the multiple analyses (i.e., in only one SamplePlusMethod node). When a program reports a dilution of a sample with only a single set of selected results per original sample, then separate Analysis nodes under one SamplePlusMethod node will be used.

- The following will also have to be defined in the data requester instructions:
 - ► Samples should have a well-defined matrix identified by a MatrixID data element.
 - ► In each SamplePlusMethod node the primary analytical method applied is identified by a ClientMethodID data element.

3.1.2 Instrument QC

- Any analysis not reportable as part of the data for a sample (as defined in Section 3.1.1) is generically called instrument QC and is reported in InstrumentQC and related nodes (all nodes located below the InstrumentQC node in the hierarchy see Figure 7).
- One InstrumentQC node conveys information associated with one QC measurement, classified by a QCType data element (e.g., calibrations and instrument blanks). Analyses not directly associated with the primary analytical instrument (e.g., GPC calibrations) are also included.
- Typically, only one analysis is reported under one InstrumentQC node. However, some types of instrument QC require multiple analyses to assess a particular performance characteristic. For example, many initial calibrations require multiple analyses to assess linearity of instrument response. In this case, multiple analyses are reported under one InstrumentQC node, using AnalysisGroup nodes to report values computed from the multiple analyses. Each InstrumentQC node must be uniquely identified through the use of the LabInstrumentQCID data element.

Here is an example of how an XML file would look regarding the reporting of initial calibration data which has multiple analyses. This example, derived from the analysis of semivolatile organics using SW-846 method 8270, illustrates how analyses in one initial calibration might be reported using ONLY the Analysis and Analysis Group nodes (does not go below into the Analyte nodes).

This example XML file starts with a comment line. Please note that there are comment lines in XML format to clarify information presented in the nodes or data elements following the comment lines

3.1.3 Method

</InstrumentQC>

- A method corresponds to a defined process for the identification and quantitation of selected analytes. The analyte list for a method often corresponds to compounds or substances measurable after one analysis on one analytical instrument.
- A method should include specifications for the type, frequency, and performance criteria for QC samples.
- Details of a method are client-specific. The following SEDD Specification data elements EDDImplementation, ClientID, ClientMethodID (for the instrumental analysis), and MatrixID are used to identify, not describe, a method. This allows the reader of an EDD to look up in their own database whatever method characteristics are needed to correctly process the data. Some programs, such as the CLP, define the method to include all of

the sample processing steps. Other programs, such as SW-846, will define unique methods for each of these steps.

• The SEDD Specification defines four types of activities associated with applying a method to a sample: characterization, handling, preparation, and instrumental analysis.

Characterization

Characterization applies to the sample as received by the data generator. This includes recording or measuring characteristics such as weight, color, texture, temperature, moisture, and pH. All such data is reported in the SamplePlusMethod node using various data elements (e.g., pH, Clarity and Turbidity). Characterization might include a screening process to determine which variant of a method to apply (e.g., determining the level for Organics).

Here are two examples for reporting Characteristics.

Example 1 - Use of a Screening Method.

In a complex case (e.g., a GC screen prior to a GC/MS analysis) the details of the screen could be reported under a separate SamplePlusMethod node with a different ClientMethodID. However, it is not common to report this level of detail.

Example 2 - Reporting of % Moisture.

In some cases, a characteristic such as percent moisture can be reported in one of two possible ways. The first, and most common approach is to treat percent moisture as a characteristic property of the sample itself and report it using the PercentMoisture data element in the same SamplePlusMethod node as the sample. The second approach is to treat percent moisture as a separate test entirely. For this situation this test would then be reported in a separate SamplePlusMethod node with a separate Results node for percent moisture.

► **Handling**

Handling applies to any manipulation of the sample prior to taking an aliquot for preparation/analysis. Examples include filtering, decanting, drying, grinding, ashing, and leaching (TCLP in particular). It is common to further characterize the sample (e.g., by weight) after each handling. All such data is reported in a Handling node under the appropriate SamplePlusMethod node. Each Handling node is characterized by a ClientMethodID or HandlingType data element.

Many methods have no handling stage and no Handling node is required in these cases. Less commonly, more than one handling is done, so more than one Handling node is required.

Example:

A sample is dried and the weight is recorded in one Handling node using one HandlingType data element. In a subsequent step, the dried sample is ashed and the weight after ashing is recorded in a second Handling node with a different HandlingType data element.

▶ Preparation

Preparation applies to all processing done to an aliquot prior to instrumental analysis. The details of preparation might involve many steps (e.g., taking an aliquot, extraction, and cleanup). Most methods have a primary processing step, such as chemical extraction or separation that are part of the analysis method. The preparative steps could also be described in a separate method. The specific preparation details would normally be captured in a separate PreparationPlusCleanup node, not in the Analysis node.

A few values, such as aliquot size, dilution, and yield (radiochemistry), are often important to report for each preparation. These data can go in an Analysis or a PreparationPlusCleanup node. For analyses that require a minimum or no preparative steps, no PreparationPlusCleanup nodes would be needed.

PreparationPlusCleanup nodes are used to report specific preparation steps, especially when a separate method is used to describe this activity. These are similar to Handling nodes in that there might be none, one, or several, depending on the method. The difference is that a PreparationPlusCleanup node applies to one aliquot used in a preparation, while a Handling node applies to one sample prior to taking an aliquot.

The ClientMethodID or CleanupType data element in the PreparationPlusCleanup node is used to characterize the cleanup.

► <u>Instrumental Analysis</u>

Instrumental analysis, more generally called the determinative step, is where measurements are made for a list of analytes. Values such as instrument identification and date analyzed are reported in the Analysis node. Analyte-specific

values from this analysis are reported in Analyte nodes under the Analysis.

If the analytical technique involves measurements of multiple peaks per analyte (e.g., GC/MS mass spectra, multi-component GC analytes, ICP emission spectra), details can be reported in Peak nodes under each Analyte.

The following example, derived from the SW-846 Semivolatile data for Method 8270, illustrates how the various activities in one method are reported in XML format. This example uses the following Nodes: SamplePlusMethod, Handling, Analysis, and PreparationPlusCleanup. The Analyte node is not used.

This example XML file starts with a comment line. Please note that there are comment lines in XML format to clarify information presented in the nodes or data elements following the comment lines.

```

3.1.4 Method QC Sample

A QC sample suitable for reporting in SamplePlusMethod nodes is called a method QC sample (e.g., Laboratory Control Sample, Method Blank, Matrix Spike). Its matrix should be well defined. Results are normally reported in the same units (exceptions would include serial dilutions and post-digestion spikes) for associated regular samples.

Method QC samples are a component of performance-based evaluation of analytical data.

• No handling may be associated with Method QC samples. However, they are prepared in the same manner as regular samples.

The following example, derived from the SW-846 method 8270 semivolatile data, shows how results and QC values for a spiked analyte are reported for a matrix spike sample.

The following nodes are used: SamplePlusMethod and ReportedResult.

This example XML file starts with a comment line. Please note that there are comment lines in XML format to clarify information presented in the nodes or data elements following the comment lines

      <ResultUnits>ug/L</ResultUnits>
      <PercentRecovery>71.1</PercentRecovery>
   </ReportedResult>
</SamplePlusMethod>
```

3.1.5 Analysis

The SEDD Specification defines an analysis as one complete sequence of events starting with an aliquot or prepared sample, perhaps involving preparation, and including an instrumental analysis. This information would be captured in the Analysis node and nodes that are nested under the SEDD Specification hierarchy. An analysis may be part of a method applied to a sample or part of an instrumental QC process. Thus Analysis nodes are present under both the SamplePlusMethod node and the InstrumentQC node.

3.1.6 Results

• The final results of a method are always reported in ReportedResult nodes. Intermediate results underlying the final results are reported in Analyte nodes. These final results take into consideration any dilutions or percent moisture calculations that would be needed.

NOTE: In the simple case of only one analysis per method, the same values could be reported in both ReportedResult and Analyte nodes. The ReportedResult nodes are required. The Analyte nodes are optional and might be used to report intermediate measurements

- The SEDD Specification distinguishes between the result of a method (e.g., reported concentration of benzene of 250 ug/L in a groundwater sample by Method 8260) and the result of an analysis (e.g., serial dilution for metals). Method results are reported in ReportedResult nodes directly under the SamplePlusMethod node. Analysis results can be reported in Analyte nodes under Analysis nodes or in Peak nodes under Analyte nodes.
- Because InstrumentQC does not have a method-like result, no ReportedResult nodes are used.
- Certain analytes in certain methods are always measured on a per-analysis, not per-method, basis (e.g., surrogates and internal standards). They should be reported in Analyte nodes, not under ReportedResult nodes. For example: in the analysis of pesticides there are separate surrogate recoveries computed for each column and surrogate analyte, which must be reported in Analyte nodes.
- Whenever more than one analysis is performed, either the data element LabAnalysisID or the data element AnalysisGroupID must be used. The data element LabAnalysisID must be used to link each reported result to the SINGLE underlying Analysis data used to produce that result. The LabAnalysisID data element must be present in both the Analysis node and ReportedResult node. If each reported result is calculated from

MULTIPLE underlying Analysis data, then the AnalysisGroupID data element must be used. See Section 3.2.2 for a complete discussion of analysis groups.

- There are three ways to report sample reanalysis data:
 - 1) If the lab is to report two sets of results, two SamplePlusMethod nodes should be used.
 - 2) If the lab is to pick one "best" result for each analyte, use one SamplePlusMethod node. The LabAnalysisID data element would be used to link each result to the correct underlying analysis.
 - 3) If the data requester requires all potential results in addition to the selected result(s), use Analyte nodes to report them under each Analysis node.

The following example, derived from the SW-846 Inorganics data, illustrates how both final and intermediate results can be reported for one soil sample.

This example XML file starts with a comment line. Please note that there are comment lines in XML format to clarify information presented in the nodes or data elements following the comment lines.

```

3.2 RELATIONSHIPS

3.2.1 Batches

• The SEDD Specification uses the concept of a batch as the primary mechanism for associating QC samples with regular ones. Analytical data review requires this association to assess the impact of QC sample performance to the quality of the regular sample results.

For example, when doing volatiles by GC/MS, it is common practice to tune the instrument, calibrate it, and analyze a blank once every shift. In this case, the SEDD Specification uses the concept of the AnalysisBatch data element to associate all the analyses done in one shift. All three QC analyses (tune, calibration, and blank) are associated with all regular sample analyses in that shift by having a common value for the AnalysisBatch data element that occurs in each of their Analysis nodes.

- The actual value used for the AnalysisBatch data element corresponding to one shift is not specified by the SEDD Specification, only that the value must be the same for all analyses in one shift and different for analyses in different shifts. The basis of the value for the AnalysisBatch data element must be given in the instructions provided by the data requester.
- The SEDD Specification uses the following eleven (11) data elements to define Batches:

AnalysisBatch

A group of analyses done on one instrument under the control of one continuing calibration or continuing calibration verification. Calibration is used in a generic sense. The details of what defines an AnalysisBatch depends on the method.

PreparationBatch

A group of aliquots prepared together for analysis by one method. 'Together' can imply similarity of the time, place, and manner of preparation, with details depending on the method. The notion of preparation is used in a generic sense for any activity prior to instrumental analysis. Method blanks and/or Laboratory Control Samples are often used to demonstrate that the laboratory's process is in control in each PreparationBatch.

HandlingBatch

A group of samples, not aliquots, handled together during the initial processing for analysis by one method. An example of QC in a HandlingBatch is a TCLP apparatus blank.

CleanupBatch

A group of aliquots going through a cleanup step together as part of preparation for analysis by one method. An example of QC in a CleanupBatch is a Gel Permeation Chromatography (GPC) calibration.

RunBatch

A group of analyses done on one instrument under the control of one initial calibration. Calibration is used in a generic sense. The details of what defines RunBatch depend on the method. Typically, one RunBatch includes the analyses from one or more analysis batches.

MethodBatch

A group of samples, not aliquots, with similar matrices, analyzed by one method and expected to have similar response to the method. Matrix spikes and duplicates are typical types of QC associated with a MethodBatch.

LabReportingBatch

A group of samples reported as a unit, (e.g., a CLP Sample Delivery Group). This batch is often used to define the context for definition (uniqueness) of batch values in data generated by the laboratory.

StorageBatch

A group of samples that are stored together. VOC refrigerator blanks are examples of QC associated with a StorageBatch.

ShippingBatch

A group of samples shipped in one container, such as a crate, cooler, or ice chest. Trip and temperature blanks are examples of QC associated with a ShippingBatch.

EquipmentBatch

A group of samples collected using the same equipment in a defined period of time. Rinsate blanks are examples of QC associated with an EquipmentBatch.

SamplingBatch

A group of samples collected together. Field blanks are examples of QC associated with a SamplingBatch.

The following example shows how a regular field sample is linked to the preparation, run, and analysis batches when implemented according to SW-846 Method 8270 (Semivolatile) rules.

This example XML file starts with a comment line. Please note that there are comment lines in XML format to clarify information presented in the nodes or data elements following the comment lines.

```

As can be seen, the Client Sample ID "S001" is linked to 3 batches as follows:

- To the intial calibration and associated tune by the data element RunBatch containing the value "first run batch."
- To the continuing calibration verification and associated tune by the data element AnalysisBatch containing the value "second analysis batch."
- To the Method QC samples (Matrix Spike, Matrix Spike Duplicate, and Method Blank) by the data element PreparationBatch containing the value "first preparation batch."

3.2.2 Analysis Groups

- Some methods may require several analyses to calculate one result (e.g., Total Organic Carbon (TOC), method of standard additions). Further, some methods may allow several potential results to be calculated, with an average final result selected for reporting as the "final result." An example using the Method of Standard Additions is given below.
- The SEDD Specification uses AnalysisGroup nodes under the SamplePlusMethod node to associate several analyses underlying one set of possible results.
- AnalysisGroup nodes under the InstrumentQC node are also used to link several analyses (e.g., multipoint initial calibrations) that are part of one instrument QC process.
- The AnalysisGroupID data element must be present in the following three nodes AnalysisGroup, Analysis, and ReportedResult.

The following example, derived from the SW-846 Inorganics data, illustrates a complex method requiring AnalysisGroup nodes. Data is shown for only one analyte and many less important data elements are omitted. In this example, the method of standard additions (MSA) was performed on the field soil sample "BH-0945Q."

This example XML file starts with a comment line. Please note that there are comment lines in XML format to clarify information presented in the nodes or data elements following the comment lines.

   <LabAnalysisID>GFAA-TL1-981015-29</LabAnalysisID>
   <AnalysisType>MSA1</AnalysisType>
   <Analyte>
      <Cli>entAnalyteID>7440-28-0</ClientAnalyteID>
      <ExpectedResult>3.5</ExpectedResult>
      <Result>13</Result>
      <ResultUnits>ug/L</ResultUnits>
   </Analyte>
</Analysis>
<!-- Third MSA analysis: -->
<Analysis>
   <AnalysisGroupID>First Analysis Group</AnalysisGroupID>
   <LabAnalysisID>GFAA-TL1-981015-30</LabAnalysisID>
   <AnalysisType>MSA2</AnalysisType>
   <Analyte>
      <ClientAnalyteID>7440-28-0</ClientAnalyteID>
      <ExpectedResult>7.0</ExpectedResult>
      <Result>17</Result>
      <ResultUnits>ug/L</ResultUnits>
   </Analyte>
</Analysis>
<!-- Fourth MSA analysis: -->
<Analysis>
   <AnalysisGroupID>First Analysis Group</AnalysisGroupID>
   <LabAnalysisID>GFAA-TL1-981015-31</LabAnalysisID>
   <AnalysisType>MSA3</AnalysisType>
   <Analyte>
      <Cli>entAnalyteID>7440-28-0</ClientAnalyteID>
      <ExpectedResult>10.5</ExpectedResult>
      <Result>21</Result>
```

```
<ResultUnits>ug/L</ResultUnits>
</Analyte>
</Analysis>
</SamplePlusMethod>
```

As can be seen, the Client Sample ID "BH-0945Q" has been analyzed using the Method of Standard Additions to determine its final Thallium Result "1.58" with ResultUnits "mg/kg". The final reported result is linked to the data element AnalysisGroup with a value of "First Analysis Group" instead of to a single analysis (which would have used the data element LabAnalysisID). All the MSA Analyses are similarly linked to each other and the final result through this same data element AnalysisGroupID having the value "First Analysis Group".

3.2.3 QC Categories and QC Linkage

- The QCCategory and QCLinkage data elements (under the SamplePlusMethod and InstrumentQC nodes see Figures 10 and 11) support cross-program movement of data (e.g., supply data for processing by different site's data validation programs) and development of implementation-independent EDD processing software. Because values for both the QCCategory and QCLinkage data elements are given by the SEDD Specification, processing software can 'understand' how to store, report, and associate a method-level QC sample.
- The QCCategory data element specifies the type of QC values and comparisons appropriate to a method-level QC sample (one reportable in a SamplePlusMethod node). Allowed values for this data element are given below.
- The QCLinkage data element specifies the type of batch used to make associations for a QC sample.
- Allowed values for the QCLinkage data element are the names of the various batch fields defined by the SEDD Specification (in Section 3.2.1). Because there are potentially multiple handling nodes for each sample, if the QCLinkage data element value is HandlingBatch, a ClientMethodID or HandlingType data element must be specified for the QC sample to make the linkage unambiguous. Similarly, a ClientMethodID or CleanupType data element must be specified if the QCLinkage data element value is CleanupBatch.
- Allowed values for QCCategory data element are:

Blank

A QC sample made to contain negligible (or unmeasurable) quantities of the analyte(s) of

interest. Detection of an analyte in a blank is an indication of contamination. Data is similar to that for a regular sample. This same QCCategory would be used with many QCTypes (e.g., those corresponding to method, trip, rinsate, field, and other types of implementation-defined blanks).

Blank Spike

A QC sample with a known amount (spike) added to a Blank. Data potentially includes a PercentRecovery and an ExpectedResult for each analyte for which the AnalyteType is Spike. An Interference Check Sample is a type of BlankSpike where the results for unspiked analytes are of interest.

Spike

A reanalysis of a regular sample done for QC purposes with a known amount added. Data is expected to include an OriginalClientSampleID for each SamplePlusMethod node and, potentially, a PercentRecovery and an ExpectedResult for each analyte for which the AnalyteType is Spike. The OriginalClientSampleID identifies the original sample that was spiked.

Duplicate

A reanalysis of a regular sample done for QC purposes. Data is expected to include an OriginalClientSampleID for each SamplePlusMethod node and, potentially, an RPD for each analyte. The OriginalClientSampleID identifies the original sample that was reanalyzed.

This use of Duplicate is meant to include what are called a 'Splits' or "replicates', as long as only two sets of results are involved.

Serial Dilution

A diluted reanalysis of a regular sample done for QC purposes. Data is expected to include an OriginalClientSampleID and, potentially, a PercentDifference. The OriginalClientSampleID identifies the original sample that was reanalyzed.

Blank Spike Duplicate

A second analysis of a BlankSpike. Data is expected to include an OriginalClientSampleID, and, potentially, a PercentRecovery, an RPD and an ExpectedResult for each analyte for which the AnalyteType is 'Spike'. The OriginalClientSampleID identifies the BlankSpike that was reanalyzed.

Spike Duplicate

A second reanalysis of a regular sample done for QC purposes with a known spike added. Data is expected to include an OriginalClientSampleID, and, potentially, a

PercentRecovery, an RPD and an ExpectedResult for each analyte where the AnalyteType is 'Spike'. The OriginalClientSampleID identifies the regular sample that was spiked and reanalyzed. There should be another SamplePlusMethod node with QCCategory 'Spike' with the same ClientMethodID and OriginalClientSampleID.

Non-Client Sample

This type of QC sample is different than the other QC sample types normally encountered in that it is, simply, a regular sample. Many programs require that certain data be reported from the analysis of non-client samples that were prepared or analyzed with project-specific samples. This is often done to verify run sequences and to ensure that certain QC samples were analyzed at an appropriate frequency. The actual analytical results would seldom be reported.

The limited list of allowed values for QCCategory and QCLinkage data elements are part
of the SEDD Specification. They represent a choice about the types of data expected to
be reported. This choice enables the development of reasonably method-independent
database software to support performance-based verification and validation of analytical
data.

As an example, in a SamplePlusMethod node, if the QCType data element value is Lab_Duplicate, the QCCategory data element value is Duplicate, and the QCLinkage data element value is MethodBatch, then a reader will know this data is for a client-defined type of QC called a Lab_Duplicate. The reader will also know it is processed with rules typical for Duplicates and it is to be associated with other SamplePlusMethod nodes with the same value for the MethodBatch data element.

The following example shows how the QCCategory and QCLinkage data elements in the EDD help to show the type of sample being analyzed (e.g., Blank) and the linkage to a batch (e.g., Preparation) in an Inorganics analysis:

<SamplePlusMethod>

- <ClientMethodID>SW846 6010</ClientMethodID>
- <LabSampleID>ICP-WG2413-1</LabSampleID>
- <MatrixID>Soil</MatrixID>
- <QCCategory>Blank</QCCategory>
- <QCLinkage>PreparationBatch</QCLinkage>
- <QCType>Method Blank</QCType>

<Analysis>

<Pre><PreparationPlusCleanup>

A general EDD reader might not recognize the ClientMethodID data element value (SW846_6010B, specified by a specific implementation) and hence not know the meaning of the QCType data element value (Method_Blank) or even that this is ICP inorganics data. However, based on the QCCategory data element value (Blank) it knows to use blank-like rules to process this data. Based on the QCLinkage data element value (PreparationBatch) it knows to associate this QC sample with other analyses with the same value (ICP-WG2413-A) for the PreparationBatch data element.

3.2.4 Comparisons

There are two basic types of comparisons that are allowed in the SEDD Specification - Analyte Comparisons and Peak Comparisons.

Analyte Comparison

- Analyte comparisons are used to describe the effects of potentially interfering analytes on the measured analyte peak.
- Data from instrument QC checks for cross-analyte interference are reported in the AnalyteComparison node.
- A common use of AnalyteComparison node is in the reporting of ICP Interelement Correction factors where the contribution to the analyte measurement from interfering analytes is reported in data elements in AnalyteComparison nodes under a Peak node (See Figure 7). This is shown in the following example.

This example XML file starts with a comment line. Please note that there are comment lines in XML format to clarify information presented in the nodes or data elements following the comment lines.

```
<!-- ICP Interelement Correction Factors: -->
```

<InstrumentOC>

- <ClientMethodID>SW846 6010B</ClientMethodID>
- <QCType>Interanalyte Correction Factors</QCType>
- <LabInstrumentQCID>IEC 1</LabInstrumentQCID>

```
<Analysis>
      <LabAnalysisID>P2 ICP 042694</LabAnalysisID>
      <!-- Report interference with this analyte: -->
      <Analyte>
          <ClientAnalyteID>7439-92-1</ClientAnalyteID>
          <AnalyteName>Lead</AnalyteName>
          <!-- At this peak: -->
          <Peak>
             <!-- identified by integer wavelength -->
             <PeakID>220</PeakID>
             <!-- described by actual value -->
             <Wavelength>220.35</Wavelength>
          <!-- First interferent: -->
             <AnalyteComparison>
                <!-- identified by CAS number -->
                <ClientAnalyteID>7429-90-5</ClientAnalyteID>
                <AnalyteName>Aluminum</AnalyteName>
                <CorrectionFactor>0.000370</CorrectionFactor>
             </AnalyteComparison>
          </Peak>
      </Analyte>
   </Analysis>
</InstrumentQC>
```

As can be seen, during the analysis of Lead by ICP-AES, Aluminum is an interferent. Lead is identified as an analyte under the Analyte node using the data element AnalyteName. The Peak used for measurement of Lead is identified in the Peak node by the data element PeakID. Aluminum interferes with this peak and its interelement correction factor is reported in the AnalyteComparison node in the data element CorrectionFactor.

Peak Comparison

• Peak comparisons are used to compare measurements made at two or more different peaks. Peak comparisons can describe cross-peak comparisons within the same analyte (e.g., abundance ratios for tunes), between two analytes (e.g., calculating the relative

response factor (RRF) for initial and continuing calibrations or inter-peak resolutions in chromatography).

• Data from these peak comparisons are reported in the PeakComparison node (see Figures 6 and 7).

One common example for using PeakComparison nodes (given below) is for the reporting of GC/MS tune data where only a single analyte is involved.

This example XML file starts with a comment line. Please note that there are comment lines in XML format to clarify information presented in the nodes or data elements following the comment lines.

```
<!-- Part of the data for one tune: -->
<InstrumentQC>
   <ClientMethodID>SW846 8270C</ClientMethodID>
   <OCType>Instrument Performance Check</OCType>
   <LabInstrumentQCID>Tune 1</LabInstrumentQCID>
   <Analysis>
      <LabAnalysisID>SV417</LabAnalysisID>
      <Analyte>
         <ClientAnalyteID>5074-71-5</ClientAnalyteID>
         <AnalyteName>DFTPP</AnalyteName>
         <AnalyteType>System Monitoring Compound/AnalyteType>
         <!-- One mass spectral peak: -->
         <Peak>
            <!-- identified by nominal mass -->
            <PeakID>68</PeakID>
            <!-- First comparison: -->
            <PeakComparison>
                <PeakID>198</PeakID>
                <PercentRatio>0.0</PercentRatio>
            </PeakComparison>
```

As can be seen in the above example, a DFTPP tune (for method SW-846 8270 semivolatile organics) is being reported under the Analyte node using the data element AnalyteName. The peak (mass number 68) to be evaluated is identified under the Peak node using the data element PeakID. This peak (mass number 68) is compared to the following two peaks (mass numbers 198 and 69) under separate PeakComparison nodes using the data element PeakID. The data element PercentRatio is used to report the actual comparison (expressed as a percent ratio).
